These insects can sense heat coming from warm animals. They land on these animals and feed on their blood.

These mammals use echoes to find their favourite flower. This is called echolocation.

These insects can see a colour called ultraviolet.

The flowers look bright and shiny. This makes it easy for the insect to find.

The sound bounces off the flower so the mammal can tell where it is.

The flower makes itself warm.
The insect is tricked into thinking the flower is an animal.
